"Can we predict how proteins will fold?"

This question was listed in 2005 as one of the 125 most important unsolved problems in science by the *Science* magazine

So much more to know.... *Science 309*, 78-102 (2005).

Atomic-Level Characterization of the Structural Dynamics of Proteins

David E. Shaw,[1,2]* Paul Maragakis,[1]† Kresten Lindorff-Larsen,[1]† Stefano Piana,[1]† Ron O. Dror,[1] Michael P. Eastwood,[1] Joseph A. Bank,[1] John M. Jumper,[1] John K. Salmon,[1] Yibing Shan,[1] Willy Wriggers[1]

SCIENCE VOL 330 15 OCTOBER 2010

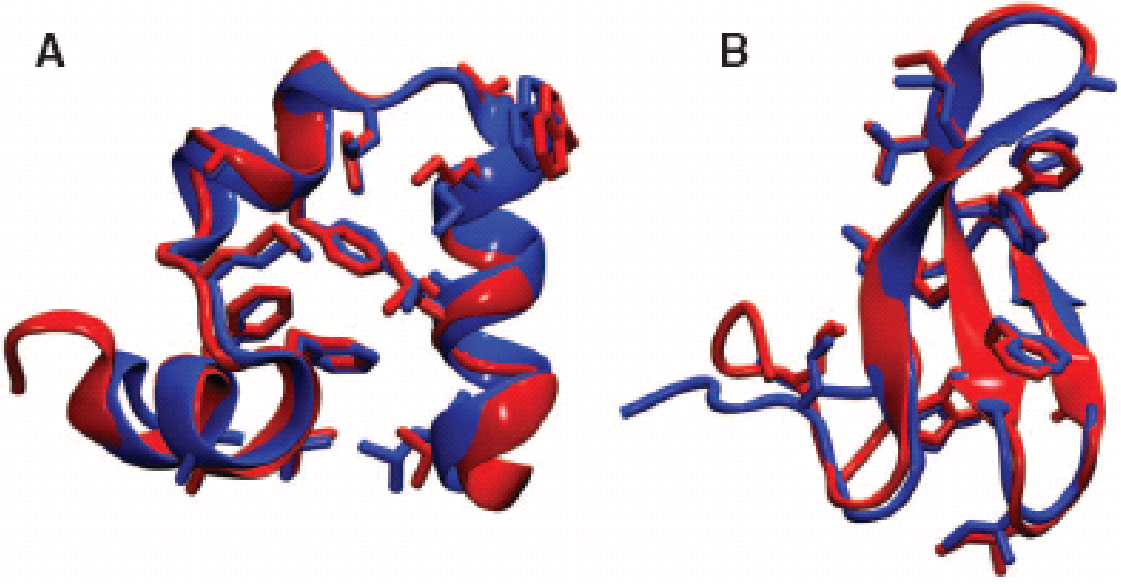

Fig. 1. Folding proteins at x-ray resolution, showing comparison of x-ray structures (blue) (*15*, *24*) and last frame of MD simulation (red): (**A**) simulation of villin at 300 K, (**B**) simulation of FiP35 at 337 K. Simulations were initiated from completely extended structures. Villin and FiP35 folded to their native states after 68 μs and 38 μs, respectively, and simulations were continued for an additional 20 μs after the folding event to verify the stability of the native fold.

Part I

Combining AFM-based single-molecule force spectroscopy (SMFS) with steered molecular dynamics simulations to examine vectorial folding of proteins

Part II

Developing protein-based SMFS probes for characterizing the strength of protein-protein interactions

Part III

Creating novel protein constructs with unusual folding and mechanical properties and engineering protein based materials

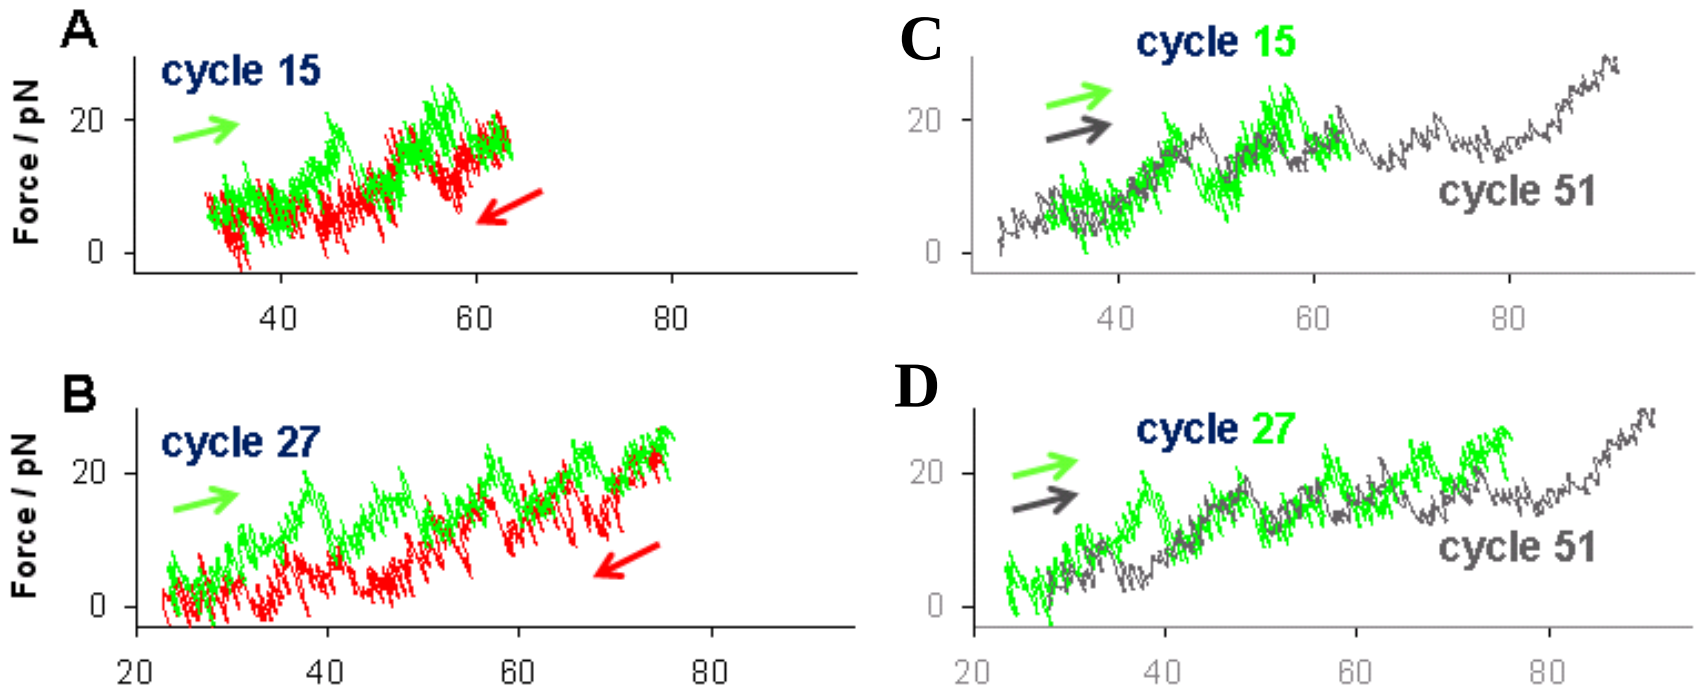
Cyclic stretch-relax measurements



Protein mechanics und unfolding can be studied by computer simulations (molecular dynamics)

An Introduction to Molecular Dynamics Simulations

Macroscopic properties are often determined by molecule-level behavior.

Quantitative and/or qualitative information about macroscopic behavior of macromolecules can be obtained from simulation of a system at atomistic level.

Molecular dynamics simulations calculate the motion of the atoms in a molecular assembly using Newtonian dynamics to determine the net force and acceleration experienced by each atom. Each atom i at position r_i, is treated as a point with a mass m_i and a fixed charge q_i.

Energy Functions

$$U(\vec{R}) = \underbrace{\sum_{bonds} k_i^{bond}(r_i - r_0)^2}_{U_{bond}} + \underbrace{\sum_{angles} k_i^{angle}(\theta_i - \theta_0)^2}_{U_{angle}} +$$

$$\underbrace{\sum_{dihedrals} k_i^{dihe}[1 + \cos(n_i\phi_i + \delta_i)]}_{U_{dihedral}} +$$

$$\underbrace{\sum_i \sum_{j \neq i} 4\epsilon_{ij}\left[\left(\frac{\sigma_{ij}}{r_{ij}}\right)^{12} - \left(\frac{\sigma_{ij}}{r_{ij}}\right)^{6}\right] + \sum_i \sum_{j \neq i} \frac{q_i q_j}{\epsilon r_{ij}}}_{U_{nonbond}}$$

U_{bond} = oscillations about the equilibrium bond length
U_{angle} = oscillations of 3 atoms about an equilibrium angle
$U_{dihedral}$ = torsional rotation of 4 atoms about a central bond
$U_{nonbond}$ = non-bonded energy terms (electrostatics and Lenard-Jones)

MD: Verlet Method

Energy function: $U(\vec{r}_1, \vec{r}_2, \cdots \vec{r}_N) = U(\vec{R})$

used to determine the force on each atom:

$$m_i \frac{d^2 \vec{r}_i}{dt^2} = \vec{F}_i = -\vec{\nabla} U(\vec{R})$$

Newton's equation represents a set of N second order differential equations which are solved numerically at discrete time steps to determine the trajectory of each atom.

$$\vec{r}_i(t + \Delta t) = 2\vec{r}_i(t) - \vec{r}_i(t - \Delta t) + \frac{\Delta t^2}{m_i} \vec{F}_i(t)$$

Steered Molecular Dynamics

$$U_{tot} = U_{internal} + U_{harmonic\ (AFM)}$$

$$U_{harmonic} = \frac{1}{2} k \left[vt - \left(\vec{r} - \vec{r_o} \right) \cdot \vec{n} \right]^2$$

Part I CONCLUSIONS

Vectorial, sequential folding may be a common feature of alpha helical stacked repeat proteins

Native contacts topology dictates folding pathways of ankyrin repeat proteins

Ankyrin repeat proteins fold via nucleation of several repeats (nucleation may depend on the residual structure in the unfolded chain)

AFM refolding of repeat proteins occurs under 1D constraints, therefore it may reproduce the folding of the Nascent Polypeptide Chain
